

Peer review: Helping-Hands

What's good

- The models are well thought out. Seven models with sensible relationships, and details like `on_delete=PROTECT` on `Category` and `unique_together` on `JobApplication` show you have thought about what happens when data gets deleted or reused.
- Splitting users into requesters and helpers is a smart design choice. It creates genuinely different flows through the app, different dashboards, different redirects after signup, different permissions on jobs.
- The access control in the views is solid. You can't complete a job unless you're the requester, can't message a thread unless you're one of the two parties, can't leave a duplicate review.
- The admin setup is clean. Every model has `list_display`, `list_filter`, and `search_fields` configured, and `Job` even allows inline status editing.
- The messaging system and report feature are nice additions. A per-job thread between requester and helper, plus the ability to report someone, both make sense for a marketplace app and go beyond the minimum requirements.

Improvements

- No `requirements.txt` or data dump in the repo. The brief explicitly requires both, and they're listed on the submission checklist. The `seed_data.py` command suggests test data exists, but a proper fixture (`manage.py dumpdata > db.json`) needs to be committed so the app can actually be run by whoever is grading it. This is the most important thing to fix before submission.
- The static folder could use a bit more. Bootstrap is clearly loaded via CDN which is fine, but there are no custom static files committed at all. The brief mentions CSS, images, and JS as expected static assets, so adding even a small `style.css` with a few overrides would tick that box properly (optional).
- The login view doesn't show errors when login fails. It manually calls `authenticate()` and `login()` rather than using Django's `AuthenticationForm`, which means if someone types the wrong password they get no feedback at all. Rendering the form properly or adding a manual error message to the template would fix this.

Overall, this is a strong project. The concept is creative, the code is readable, and the feature set is genuinely complete. Once the static files and repo requirements are sorted it'll be in really good shape.
